Multi-level parallelism

Final words as time permits

# "Unzipped" SOACs

### Representation

```
An array [](t1, t2, t3...) is represented in memory as ([]t1, []t2, []t3...), i.e. as multiple arrays, each containing only primitive values.
```

Instead of

we write

**let** 
$$(xs, ys) = map (\x y -> (x-1, y+1)) xs ys$$

- In the compiler, All SOACs accept multiple inputs and produce unzipped results.
- Arrays of tuples (or records, or sums) do not exist in the core language.
- Isomorphic to source language, but this form is simpler in a compiler.

### **Loop fusion**

```
def increment [n][m] (as: [n][m]i32) : [n]i32 =
  map (\r -> map (+2) r) a
def sum [n] (a: [n]i32) : i32 =
  reduce (+) 0 a
def sumrows [n][m] (as: [n][m]i32) : [n]i32 =
  map sum as
```

Suppose we wish to first call increment, then sumrows:

```
sumrows (increment a)
```

Naively Run increment, then call sumrows.

Problem Manifests intermediate matrix in memory.

Solution *Loop fusion*, which combines loops to avoid intermediate results.

## An example of a fusion rule

The expression

is always equivalent to

**map** 
$$(f \circ g)$$
  $a$ 

- This is an extremely powerful property that is only true in the absence of side effects.
- Fusion is the core optimisation that permits the efficient decomposition of a data parallel program.
- A full fusion engine has much more awkwark rules (mostly bookkeeping related to fusing only some of several inputs), but safety is guaranteed.

## A fusion example

```
sumrows (increment a) = (Initial expression)

map sum (increment a) = (Inline sumrows)

map sum (map (\lambda r \rightarrow \text{map}(+2) r) a) = (Inline increment)

map (sum \circ (\lambda r \rightarrow \text{map}(+2) r) a) = (Apply map-map fusion)

map (\lambda r \rightarrow \text{sum}(\text{map}(+2) r) a) = (Apply composition)
```

- We have avoided the temporary matrix, but the composition of sum and the map also holds an opportunity for fusion – specifically, reduce-map fusion.
- Will not cover in detail, but a reduce can efficiently apply a function to each input element before engaging in the actual reduction operation.
- Important to remember: a **map** going into a **reduce** is an efficient pattern.

# A shorthand notation for sequences

$$\overline{z}^{(n)}=z_0,\cdots,z_{(n-1)}$$

- The *n* may be omitted.
- A separator may be implied by context.

$$f \, \overline{v}^{(n)} \equiv f \, v_1 \, \cdots \, v_n$$

or a tuple

$$(\overline{v}^{(n)}) \equiv (v_1, \ldots, v_n)$$

or a function type

$$\overline{\tau}^{(n)} \to \tau_{n+1} \equiv \tau_1 \to \cdots \to \tau_n \to \tau_{n+1}.$$

When not all terms under the bar are variant, subscript variant terms with i.

$$(\overline{[d]v_i}^{(n)}) = ([d]v_1, \dots, [d]v_n)$$

and

$$(\overline{[d_i]v_i}^{(n)})=([d_1]v_1,\ldots,[d_n]v_n)$$

### **Fused constructs**

### Convenient shorthands

$$\begin{array}{ll} \mathbf{redomap} \ \odot \ f \ (\overline{d}) \ \overline{\mathit{xs}} \equiv & \mathbf{reduce} \ \odot \ (\overline{d}) \ (\mathsf{map} \ f \ \overline{\mathit{xs}}) \\ \\ \mathbf{scanomap} \ \odot \ f \ (\overline{d}) \ \overline{\mathit{xs}} \equiv & \mathbf{scan} \ \odot \ (\overline{d}) \ (\mathsf{map} \ f \ \overline{\mathit{xs}}) \end{array}$$

- Emphasises that reduce/scan-map compositions can be considered as a single construct.
- We will see several examples where this is useful.

### Fused constructs

### Convenient shorthands

- Emphasises that reduce/scan-map compositions can be considered as a single construct.
- We will see several examples where this is useful.

**redomap**  $\odot$   $f(\overline{d}) \overline{xs} \equiv$ 

#### Note:

```
reduce \odot (\overline{d}) \overline{xs} \equiv reduce \odot (\overline{d}) (\text{map id } \overline{xs}) \equiv
                                                                                                                                             redomap \odot id (\overline{d}) \overline{xs}
       \operatorname{scan} \odot (\overline{d}) \overline{xs} \equiv \operatorname{scan} \odot (\overline{d}) (\operatorname{map} \operatorname{id} \overline{xs}) \equiv \operatorname{scanomap} \odot \operatorname{id} (\overline{d}) \overline{xs}
```

Representation and Fusion

### Handling nested parallelism

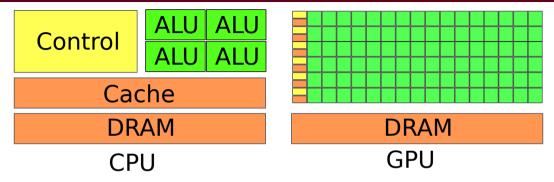

Basic flattening rules

Incremental flattening

Multi-level parallelism

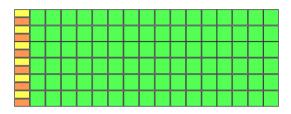

Final words as time permits

## **GPUs vs CPUs**

- GPUs have thousands of simple cores and taking full advantage of their compute power requires tens of thousands of threads.
- GPU threads are very restricted in what they can do: no stack, no allocation, limited control flow, etc.
- Potential very high performance and lower power usage compared to CPUs, but programming them is hard.

# The SIMT Programming Model

- GPUs are programmed using the SIMT model (*Single Instruction Multiple Thread*).
- Similar to SIMD (Single Instruction Multiple Data), but while SIMD has explicit vectors, we provide sequential scalar per-thread code in SIMT.

Each thread has its own registers, but they all execute the same instructions at the same time (i.e. they share their instruction pointer).

## SIMT example

For example, to increment every element in an array a, we might use this code:

```
increment(a) {
  tid = get_thread_id();
  x = a[tid];
  a[tid] = x + 1;
}
```

- If a has n elements, we launch n threads, with get\_thread\_id() returning i for thread i.
- This is *data-parallel programming*: applying the same operation to different data.
- When we launch a GPU program (*kernel*), we say how many threads should be launched, *all running the same code*.

## **Branching**

If all threads share an instruction pointer, what about branches?

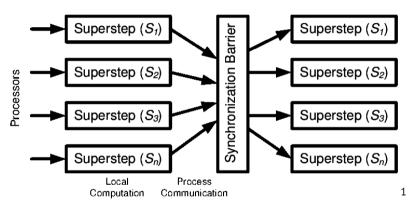

```
mapabs(a) {
  tid = get_thread_id();
  x = a[tid];
  if (x < 0) {
    a[tid] = -x;
  }
}</pre>
```

#### Masked Execution

Both branches are executed in all threads, but in those threads where the condition is false, a mask bit is set to treat the instructions inside the branch as no-ops.

# Do GPUs exist in theory as well?

GPU programming is a close fit to the *bulk synchronous parallelism* model:

- Supersteps are threads, which cannot talk to each other.
- The synchronisation barriers are kernel launches.

<sup>&</sup>lt;sup>1</sup>Illustration by Aftab A. Chandio.

### A SOAC-kernel correspondence

The compiler *knows*<sup>2</sup> that certain nestings of **map**s correspond to GPU basic blocks.

- maps containing scalar code is a kernel with one thread per iteration of the maps.
- **map**s containing a single **reduce** is a *segmented reduction*.
- **map**s containing a single **scan** is a *segmented scan*.
- maps containing a single scatter is a segmented scatter.
- ...see the pattern?

**Crucial**: the **map**s must be *perfectly nested* around the operation.

### Perfect nesting of an operation $e_o$

An expression e is a perfect nesting of  $e_0$  if e has form

map 
$$(\lambda \overline{p} \rightarrow e_f) \overline{x}$$

where either  $e_f = e_0$  or  $e_f$  is a perfect nesting of  $e_0$ .

<sup>&</sup>lt;sup>2</sup>Because it was taught it by Cosmin in PMPH.

### **Example**

- Suppose xss is of shape [n][m].
- This could be compiled to a kernel with  $n \times m$  threads, each doing a single x + y operation.

# Handling nested parallelism

### Problem

Futhark permits *nested* parallelism, but GPUs need *flat* parallel *kernels*.

# Handling nested parallelism

#### Problem

Futhark permits *nested* parallelism, but GPUs need *flat* parallel *kernels*.

#### Solution

Have the compiler rewrite program to perfectly nested **map**s containing sequential operations, or known parallel patterns such as segmented reduction.

# Handling nested parallelism

#### Problem

Futhark permits *nested* parallelism, but GPUs need *flat* parallel *kernels*.

#### Solution

Have the compiler rewrite program to perfectly nested **map**s containing sequential operations, or known parallel patterns such as segmented reduction.

# Flattening via loop fission

The classic map fusion rule:

$$\mathsf{map}\, f \circ \mathsf{map}\; g \Rightarrow \mathsf{map}\; (f \circ g)$$

<sup>&</sup>lt;sup>3</sup> Futhark: Purely Functional GPU-Programming with Nested Parallelism and In-Place Array Updates, PLDI 2017

# Flattening via loop fission

The classic map fusion rule:

$$\mathsf{map}\, f \circ \mathsf{map}\; g \Rightarrow \mathsf{map}\; (f \circ g)$$

We can also apply it backwards to obtain fission:

$$\mathsf{map}\; (f\circ g)\Rightarrow \mathsf{map}\; f\circ \mathsf{map}\; g$$

This, along with other fission rules (see paper<sup>3</sup>), are applied by the compiler to extract perfect map nests.

<sup>&</sup>lt;sup>3</sup> Futhark: Purely Functional GPU-Programming with Nested Parallelism and In-Place Array Updates, PLDI 2017

# Example: (a) Initial program, we inspect the map-nest

```
let (asss. bss) =
  map (\( ps: [m]i32 \) \rightarrow
         let ass = map (\((p: i32): [m]i32 ->
                            let cs = scan (+) 0 (iota p)
                            let r = reduce (+) 0 cs
                            in map (+r) ps) ps
         let bs = loop ws=ps for i < n do
                       map (\as w: i32 \rightarrow
                              let d = reduce (+) 0 as
                              let e = d + w
                              in 2 * e) ass ws
         in (ass, bs)) pss
We assume the type of pss : \lceil m \rceil \lceil m \rceil i 32.
```

### (b) Distribution

```
let asss: [m][m][m]i32 =
 map (\( ps: [m]i32 \) \rightarrow
        let ass = map (\((p: i32): [m]i32 ->
                           let cs = scan (+) 0 (iota p)
                           let r = reduce (+) 0 cs
                           in map (+r) ps) ps
        in ass) pss
let bss: [m][m]i32 =
 map (\setminus ps ass ->
        let bs = loop ws=ps for i < n do
                      map (\setminus as w ->
                             let d = reduce (+) 0 as
                             let e = d + w
                             in 2 * e) ass ws
        in bs) pss asss
```

## (c) Interchanging outermost map inwards

```
let asss: [m][m][m]i32 =
 map (\( ps: [m]i32 \) \rightarrow
         let ass = map (\((p: i32): [m]i32 ->
                           let cs = scan (+) 0 (iota p)
                           let r = reduce (+) 0 cs
                           in map (+r) ps) ps
        in ass) pss
let bss: [m][m]i32 =
 map (\ps ass \rightarrow
         let bs = loop ws=ps for i < n do
                      map (\setminus as w ->
                             let d = reduce (+) 0 as
                             let e = d + w
                             in 2 * e) ass ws
         in bs) pss asss
```

## (c) Interchanging outermost map inwards

```
let asss: [m][m][m]i32 =
 map (\( ps: [m]i32 \) \rightarrow
         let ass = map (\((p: i32): [m]i32 \rightarrow
                           let cs = scan (+) 0 (iota p)

# (g) Cannot distribute as it would create irregular array

Array cs has type [p]i32, and p is variant to the innermost map nest.

# (h) These statements are sequentialised

Array cs has type [p]i32, and p is variant to the innermost map nest.

### Result

- From a single kernel with parallelism m to four kernels of parallelism  $m^2$ ,  $m^3$ ,  $m^3$ , and  $m^2$ .
- The last two kernels are executed *n* times each.

Representation and Fusion

Handling nested parallelism

### Basic flattening rules

Incremental flattening

Multi-level parallelism

Final words as time permits

# Notation for flat parallelism

### Instead of

we write

```
\begin{array}{l} \textbf{segmap} \; (\langle \texttt{ps}, \texttt{rs} \in \texttt{pss}, \texttt{rss} \rangle, \; \langle \texttt{r} \in \texttt{rs} \rangle, \; \langle \texttt{p} \in \texttt{ps} \rangle) \\ e \end{array}
```

# Segmented flat parallel constructs

$$\Sigma = \Sigma' \ \langle \overline{x} \in \overline{y} 
angle$$
 segmap  $\Sigma \ e \equiv \mod(\lambda \overline{x_p} o \max_{oldsymbol{map}} (\lambda \overline{x_{p-1}} o \ldots \max_{oldsymbol{map}} (\lambda \overline{x_1} o e) \ \overline{y_1})$   $\overline{y_p}$ 

- Conceptually a perfect nest of **map**s with some operation inside.
- *These* are what trigger GPU code generation.
- Any SOACs left in e will be executed sequentially.

# Similarly for reductions and scans

```
segred \Sigma \odot \overline{d} e \equiv \mathsf{map} (\lambda \overline{X_p} \rightarrow \mathsf{map} (\lambda \overline{X_p}))
                                                                         map (\lambda \overline{X_{p-1}} \rightarrow \dots)
                                                                                redomap \odot (\lambda \overline{x_1} \rightarrow e) (\overline{d}) \overline{y_1})
                                                                                \overline{y_{p-1}}
seqscan \Sigma \odot \overline{d} e \equiv \text{map} (\lambda \overline{x_n} \rightarrow
                                                                         map (\lambda \overline{X_{p-1}} \rightarrow \dots
                                                                                scanomap \odot (\lambda \overline{x_1} \rightarrow e) \overline{d} \overline{y_1})
                                                                                \overline{y_{p-1}})
```

Let us look at how one can rewrite SOAC nests to these segmented operations.

# Functional flattening rules

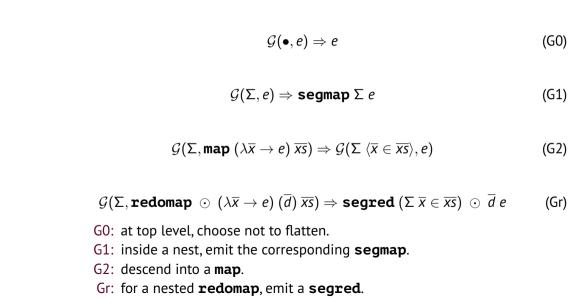

### A flattening rewrite

$$\mathcal{G}(\Sigma,e)\Rightarrow e'$$

says that flattening an operation e nested inside a map nest  $\Sigma$  produces the expression e'.

- Rewrite rules define which rewrites are valid.
- Not an algorithm: multiple rewrites are often possible.
- Form in is a bit different and have more details; I have tried to keep it more high level.

# Basic rules

### **Distribution rule**

$$\mathcal{G}(\Sigma, \mathbf{let} \ \overline{a_0} = e_1 \ \mathbf{in} \ e_2) \Rightarrow \mathbf{let} \ \overline{a_p} = \mathcal{G}(\Sigma, e_1) \ \mathbf{in} \ \mathcal{G}(\Sigma', e_2)$$
 (G6)

where

$$\begin{array}{rcl} \Sigma & = & \langle \overline{x_p} \in \overline{y_p} \rangle, \ldots, \langle \overline{x_1} \in \overline{y_1} \rangle \\ \Sigma' & = & \langle \overline{x_p} \, \overline{a_{p-1}} \in \overline{y_p} \, \overline{a_p} \rangle, \ldots, \langle \overline{x_1} \, \overline{a_0} \in \overline{y_1} \, \overline{a_1} \rangle \end{array}$$

and  $\overline{a_p}, \ldots, \overline{a_1}$  are fresh names.

**Note:** only applicable when each array in  $\overline{a_0}$  is invariant to  $\Sigma$ .

### **Example**

We are flattening

$$e = \text{map} (\lambda xs \rightarrow \text{let } y = \text{redomap} (+) (\lambda x \rightarrow x) 0 xs$$

$$\text{in map} (\lambda x \rightarrow x + y) xs)$$
xss

### **Example**

We are flattening

$$e = extsf{map} (\lambda xs 
ightarrow \ extsf{let} \ y = extsf{redomap} (+) (\lambda x 
ightarrow x) \ 0 \ xs$$
 in map  $(\lambda x 
ightarrow x + y) \ xs)$ 

By applying rule G1 we get

$$\mathcal{G}(\bullet,e) = \mathcal{G}(\langle \mathtt{xs} \in \mathtt{xss} \rangle, \ \mathbf{let} \ \mathtt{y} = \mathbf{redomap} \ (+) \ (\lambda \mathtt{x} \to \mathtt{x}) \ \mathtt{0} \ \mathit{xs} \ ) \\ \mathbf{in} \ \mathbf{map} \ (\lambda \mathtt{x} \to \mathtt{x} + \mathtt{y}) \ \mathtt{xs})$$

$$\mathcal{G}(\langle xs \in xss \rangle, \text{ let } y = \text{redomap } (+) (\lambda x \to x) 0 xs)$$
  
in map  $(\lambda x \to x + y) xs)$ 

Apply distribution rule by:

### Reminder: distribution rule

$$\mathcal{G}(\Sigma, \mathbf{let} \ \overline{a_0} = e_1 \ \mathbf{in} \ e_2) \Rightarrow \mathbf{let} \ \overline{a_p} = \mathcal{G}(\Sigma, e_1) \ \mathbf{in} \ \mathcal{G}(\Sigma', e_2)$$
 (G6)

### Flattening transposition

**rearrange**  $(d_1, \dots, d_n)$  x is a generalization of **transpose** in that it rearranges the dimensions of d-dimensional array based on a permutation defined by the integer sequence  $d_1, \dots, d_n$ . E.g:

$$transpose \equiv rearrange (1,0)$$

# Flattening transposition

**rearrange**  $(d_1, \dots, d_n)$  x is a generalization of **transpose** in that it rearranges the dimensions of d-dimensional array based on a permutation defined by the integer sequence  $d_1, \dots, d_n$ . E.g:

$$extbf{transpose} \equiv extbf{rearrange} (1,0)$$

### Flattening rule

$$\mathcal{G}(\Sigma \langle x \in y \rangle, \mathtt{rearrange} (k_1, \dots, k_n) \, x) \Rightarrow \mathcal{G}(\Sigma, \mathtt{rearrange} (0, 1 + k_1, \dots, 1 + k_n) \, y)$$

Eventually reaches base case where  $\Sigma = \bullet$ .

### map-loop interchange

$$\mathcal{G}(\Sigma \ \langle \overline{x} \ \overline{y} \in \overline{xs} \ \overline{ys} \rangle, \textbf{loop} \ \overline{z'} \ \overline{y'} = \overline{z} \ \overline{y} \ \textbf{for} \ i < n \ \textbf{do} \ f \ i \ \overline{q} \ \overline{x} \ \overline{y} \ \overline{y'} \ \overline{z'}) \Rightarrow \\ \mathcal{G}(\Sigma, \textbf{loop} \ \overline{zs'} \ \overline{ys'} \ = \ \overline{z'} \ \overline{ys} \ \textbf{for} \ i < n \ \textbf{do} \ \textbf{map} \ (f \ i \ \overline{q}) \ \overline{xs} \ \overline{ys} \ \overline{ys'} \ \overline{zs'})$$

where

$$m=$$
 outer size of each of  $\overline{xs}$  and  $\overline{ys}$   $\overline{z^r}=$   $\overline{\mathbf{replicate}\ m\ z_i}$   $\{n,\overline{q},\overline{z}\}\cap\{\overline{x},\overline{y}\}=$ 

and  $\overline{zs'}$  and  $\overline{ys'}$  are fresh names.

### Informal example of interchange

### Validity of interchange

The simple intuition is that

because they both produce

$$[f^n \times s[0], \dots, f^n \times s[m-1]]$$

Representation and Fusior

Handling nested parallelism

Basic flattening rules

Incremental flattening

Multi-level parallelism

Final words as time permits

# **Consider Matrix Multiplication**

```
for i < n:
    for j < m:
        acc = 0
        for l < p:
        acc += xss[i,l] * yss[l,j]
        res[i,j] = acc</pre>
```

# **Turning it Functional**

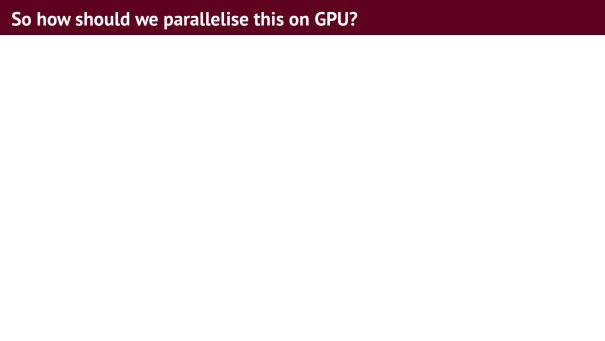

```
map (\xs ->
    map (\ys ->
        let zs = map (*) xs ys
        in reduce (+) 0 zs)
        (transpose yss))
    xss
```

# Using redomap notation

```
map (\xs ->
    map (\ys ->
        redomap (+) (*) 0 xs ys)
        (transpose yss))
xss
```

```
\mathbf{redomap} \, \odot \, f \, 0_{\odot} \, x \ \equiv \ \mathbf{reduce} \, \odot \, 0_{\odot} \, (\mathbf{map} \, f \, x)
```

Emphasises that a **map-reduce** composition can be turned into a fused tight sequential loop, or into a parallel reduction.

### So how should we parallelise this on GPU?

# Full flattening map (\xs -> map (\ys -> redomap (+) (\*) 0 xs ys) (transpose yss)) xss

- All parallelism exploited
- Some communication overhead
- Best if outer maps don't saturate GPU

### So how should we parallelise this on GPU?

### Full flattening

```
map (\xs ->
  map (\ys ->
  redomap (+) (*) 0 xs ys)
  (transpose yss))
xss
```

- All parallelism exploited
- Some communication overhead
- Best if outer maps don't saturate GPU
- There is no one size fits all.
- Both situations may be encountered at program runtime.

### Moderate flattening

```
map (\xs ->
  map (\ys ->
  redomap (+) (*) 0 xs ys)
  (transpose yss))
xss
```

- Only outer parallelism
- The redomap can be block tiled
- Best if outer maps saturate GPU

### The essence of incremental flattening

From a single source program, for each parallel construct generate multiple semantically equivalent parallelisations, and generate a single program that at runtime picks the least parallel that still saturates the hardware.

- Implemented in the Futhark compiler.
- ...but technique is applicable to any (regular) nested parallelism expressed with the common functional array combinators (map, reduce, scan, etc).

### Simple Incremental Flattening

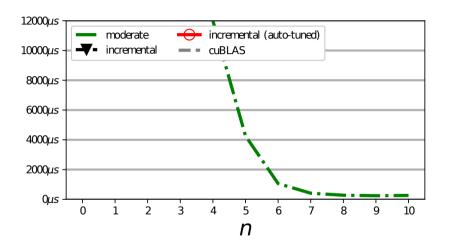

At every level of map-nesting we have two options:

- 1. Continue flattening inside the map, exploiting the parallelism there.
- 2. Sequentialise the map body; exploiting only the parallelism on top.
- Full flattening in the Blelloch style will do the former, maximising utilised parallelism.
- Incremental flattening generates both versions and uses a predicate to pick at runtime.

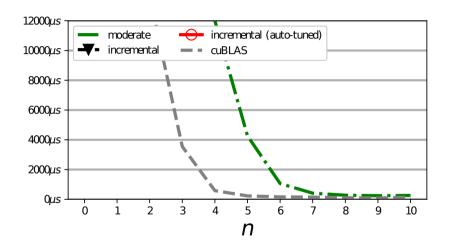

# Multi-versioned matrix multiplication

```
xss : [n][p]i32
yss : [p][m]i32.
if n * m > t_0 then
  map (\setminus xs \rightarrow
           map (\setminus vs ->
                     redomap (+) (*) 0 xs ys)
                 (transpose vss))
        XSS
else
  map (\setminus xs \rightarrow
           map (\setminus vs ->
                     redomap (+) (*) 0 xs ys)
                 (transpose yss))
        XSS
```

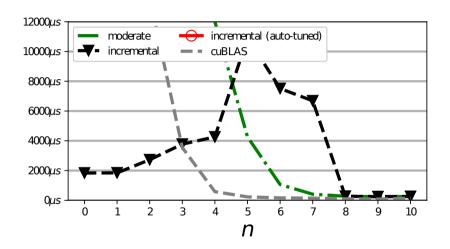

The  $t_0$  threshold parameter is used to select between the two versions—and should be auto-tuned on the concrete hardware.

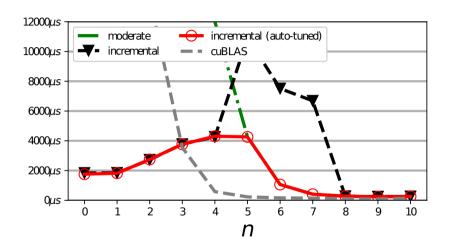

Multiplying matrices of size  $2^n \times 2^m$  and  $2^m \times 2^n$ , where m = 25 - 2n, meaning that work is constant as we vary n.

Multiplying matrices of size  $2^n \times 2^m$  and  $2^m \times 2^n$ , where m = 25 - 2n, meaning that work is constant as we vary n.

Multiplying matrices of size  $2^n \times 2^m$  and  $2^m \times 2^n$ , where m = 25 - 2n, meaning that work is constant as we vary n.

Multiplying matrices of size  $2^n \times 2^m$  and  $2^m \times 2^n$ , where m = 25 - 2n, meaning that work is constant as we vary n.

### Incremental flattening rule

where  $\Sigma' = \Sigma, \langle \overline{x} \in \overline{xs} \rangle$ .

### **Example for**

### Incremental flattening rule

$$\begin{array}{ll} \mathcal{G}(\Sigma, \text{map } (\lambda \overline{x} \to e) \ \overline{\text{xs}}) \Rightarrow & \text{if } \operatorname{Parallelism}(\Sigma') \geq t_{\operatorname{top}} \\ & \text{then segmap } \Sigma' \ e \\ & \text{else } \mathcal{G}(\Sigma', e) \end{array}$$

where  $\Sigma' = \Sigma, \langle \overline{x} \in \overline{xs} \rangle$ .

### **Example for**

### Autotuning

- An incrementally flattened program may have dozens of threshold parameters,  $t_i$ , used to select versions at runtime.
- As we have seen, the default value (2<sup>16</sup>) is often not optimal.

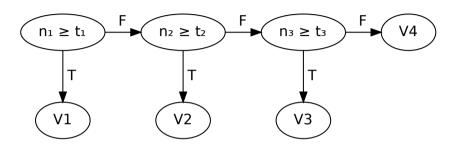

A configuration P maps each  $t_i$  to an integer  $P(t_i)$ .

### The search problem

Find the P that minimises the cost function F(P), where the the cost function runs the program on a set of user-provided representative datasets and sums the observed runtimes.

- Other cost functions are also possible, e.g. average runtime over datasets.
- Note: recompilation is not necessary.

# Briefly on the search procedure<sup>4</sup>

- Suppose we are given training data sets  $D_j$ , j < k, each of which provide a value  $v_{i,j}$  for each threshold parameter  $n_i$ .
- Starting from the deepest comparison  $(t_3)$ , for each  $D_j$  find an  $(x_j, y_j)$  that minimises runtime, take the intersection of the intervals, and use that to determine threshold value.
- Tuning time is linear in the number of comparisons.

<sup>4</sup>https://futhark-lang.org/publications/tfp21.pdf

# **Using incremental flattening**

Compile with a GPU backend (opencl or cuda):

\$ futhark opencl matmul.fut

To autotune:

\$ futhark autotune -v --backend=opencl matmul.fut

Produces matmul .fut .tuning, which is automatically picked up by futhark bench (use --no-tuning to stop this).

Use futhark dev -s --extract-kernels -e matmul.fut to see IR.

### Confession

I lied when I claimed that GPU threads were completely isolated.

#### Confession

#### I lied when I claimed that GPU threads were completely isolated.

- Most hardware has useful (fixed) levels of parallelism.
- An ideal flattening algorithm maps levels of application parallelism (any number) to hardware parallelism (fixed number) in a way that exploits locality well.

**Example of deep nesting:** a system consists of multiple *datacenters*, that each contain multiple *computers*, that each contain multiple *GPUs*, that each contain multiple *SMs* (next slide), that each run some number of threads.

### Confession

#### I lied when I claimed that GPU threads were completely isolated.

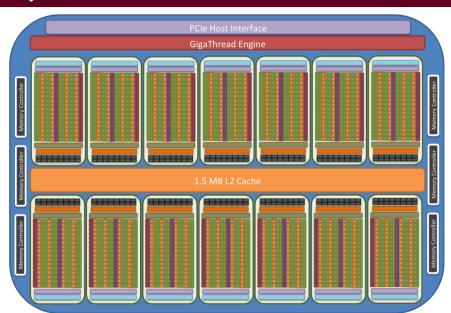

- Most hardware has useful (fixed) levels of parallelism.
- An ideal flattening algorithm maps levels of application parallelism (any number) to hardware parallelism (fixed number) in a way that exploits locality well.

**Example of deep nesting:** a system consists of multiple *datacenters*, that each contain multiple *computers*, that each contain multiple *GPUs*, that each contain multiple *SMs* (next slide), that each run some number of threads.

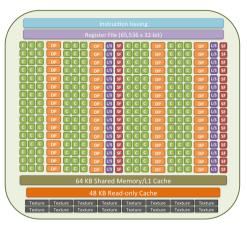

#### General principle

"Tasks" at the same hardware level cannot communicate, but can "launch" tasks at a lower level.

## **K20 GPU layout**

## Streaming Multiprocessor (SM) layout

single precision/integer CUDA core smemory load/store unit double precision FP unit special function unit

## Level-aware segmented operations

$$l \in \{\text{thread}, \text{block}\}\$$

■ Each segmented operation then tagged with the level at which its *body* executes.

$$\begin{split} & \operatorname{segmap}_{l} \Sigma \ e \\ & \operatorname{segscan}_{l} \Sigma \ \odot \ \overline{d} \ e \\ & \operatorname{segred}_{l} \Sigma \ \odot \ \overline{d} \ e \end{split}$$

#### Restrictions

Both thread and block can occur at top level, but a block construct can contain only thread constructs, and thread cannot contain any segmented constructs.

## **Examples**

#### Each thread transposes part of an array

$$segmap_{thread} \langle x \in xs \rangle$$
 (transpose x)

#### Each workgroup transposes part of an array

$$segmap_{block} \langle x \in xs \rangle$$
 (transpose x)

These are both equivalent to map transpose xs.

#### Each workgroup sums the row of an array

```
\mathbf{segmap}_{block} \ \langle \mathtt{xs} \in \mathtt{xss} \rangle \ (\mathbf{segred}_{thread} \ \langle \mathtt{x} \in \mathtt{xs} \rangle \ (+) \ 0 \ \mathtt{x})
```

Equivalent to map (reduce (+) 0) xss.

Tags carry no semantic meaning; used solely for code generation.

### **Example: LocVolCalib**

The following is the essential core of the LocVolCalib benchmark from the FinPar suite.

```
map (\xss ->
    map (\xs ->
        let bs = scan \oplus d_{\oplus} xs
    let cs = scan \otimes d_{\otimes} bs
    in scan \odot d_{\odot} cs)
    xss)
```

How can we map the application parallelism to hardware parallelism?

### **Option I: sequentialise the inner scans**

```
\begin{split} \mathbf{segmap}_{\mathrm{thread}} \; & (\langle \mathtt{xss} \in \mathtt{xsss} \rangle, \langle \mathtt{xs} \in \mathtt{xss} \rangle) \\ \mathbf{let} \; & \mathtt{bs} = \mathbf{scan} \oplus \; d_{\oplus} \; \mathtt{xs} \\ \mathbf{let} \; & \mathtt{cs} = \mathbf{scan} \otimes \; d_{\otimes} \; \mathtt{bs} \\ \mathbf{in} \; & \mathbf{scan} \; \odot \; d_{\odot} \; \mathit{cs} \end{split}
```

**scan** is relatively expensive in parallel, so this is a good option if the outer dimensions provide enough parallelism.

## **Option II: flatten and parallelise inner scans**

Flattening uses *loop distribution* (or *fission*) to create **map** nests:

```
map (\xss ->
    map (\xs ->
        let bs = scan \oplus d_{\oplus} xs
    let cs = scan \otimes d_{\otimes} bs
        in scan \odot d_{\odot} cs)
        xss)
    xsss
```

## Option II: flatten and parallelise inner scans

```
\label{eq:letbsss} \begin{split} &\textbf{segscan}_{thread} \; \big( \langle \texttt{xss} \in \texttt{xsss} \rangle, \langle \texttt{xs} \in \texttt{xss} \rangle,, \langle \texttt{x} \in \texttt{xs} \rangle \big) \; \oplus \; d_{\oplus} \; \texttt{x} \\ &\textbf{let} \; \texttt{csss} = \\ &\textbf{segscan}_{thread} \; \big( \langle \texttt{bss} \in \texttt{bsss} \rangle, \langle \texttt{bs} \in \texttt{bss} \rangle,, \langle \texttt{b} \in \texttt{bs} \rangle \big) \; \oplus \; d_{\oplus} \; \texttt{b} \\ &\textbf{in} \\ &\textbf{segscan}_{thread} \; \big( \langle \texttt{css} \in \texttt{csss} \rangle, \langle \texttt{cs} \in \texttt{css} \rangle,, \langle \texttt{c} \in \texttt{cs} \rangle \big) \; \oplus \; d_{\oplus} \; \texttt{c} \end{split}
```

This is what full flattening will do.

## Option III: Mapping innermost parallelism to the workgroup level

# Option III: Mapping innermost parallelism to the workgroup level

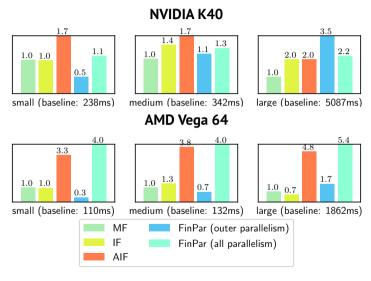

```
\begin{split} \mathbf{segmap}_{block} & \left( \langle \mathtt{xss} \in \mathtt{xsss} \rangle, \langle \mathtt{xs} \in \mathtt{xss} \rangle \right) \\ \mathbf{let} \ \mathtt{bs} &= \mathbf{segscan}_{thread} \ \langle \mathtt{x} \in \mathtt{xs} \rangle \ \oplus \ d_{\oplus} \ \mathtt{x} \\ \mathbf{let} \ \mathtt{cs} &= \mathbf{segscan}_{thread} \ \langle \mathtt{b} \in \mathtt{bs} \rangle \otimes \ d_{\otimes} \ \mathtt{b} \\ \mathbf{in} \ \mathbf{segscan}_{thread} \ \langle \mathtt{c} \in \mathtt{cs} \rangle \otimes \ d_{\otimes} \ \mathtt{c} \end{split}
```

- Iterations of outer segmaps assigned to GPU workgroups<sup>5</sup>.
- Each segscan<sub>thread</sub> is executed collaboratively by a workgroup and in local memory<sup>6</sup>.
- Only works if the innermost parallelism fits in a workgroup.

<sup>&</sup>lt;sup>5</sup>Thread block in CUDA

<sup>&</sup>lt;sup>6</sup>Shared memory in CUDA

## LocVolCalib speedup (higher is better)

Sequential scans (MF) is the baseline.

## Level-aware incremental flattening

 $\left| \mathcal{G}_l(\Sigma, e) \Rightarrow e' \right|$  In a map-nest context  $\Sigma$ , the source expression e can be translated at machine level l into the target expression e'.

$$\mathcal{G}_{l+1}(\Sigma, exttt{map}\ (\lambda \overline{x} o e)\ \overline{ exttt{xs}}) \Rightarrow \ exttt{if}\ ext{Par}(\Sigma') \geq t_{ ext{top}} \ ext{then segmap}_{l+1}\ \Sigma'\ e \ ext{else if}\ ext{Par}(e_{ ext{middle}}) \geq t_{ ext{intra}} \ ext{then segmap}_{l+1}\ \Sigma'\ \mathcal{G}_{l}(ullet, e) \ ext{else}\ \mathcal{G}_{l+1}(\Sigma', e)$$

where  $\Sigma' = \Sigma, \langle \overline{x} \in \overline{xs} \rangle$  and  $t_{top}, t_{intra}$  fresh. In the Futhark compiler, only two levels are handled (thread, block), but we believe the idea generalises well. Representation and Fusior

Handling nested parallelism

Basic flattening rules

Incremental flattening

Multi-level parallelism

Final words as time permits

### **Block tiling**

Level-aware constructs can also be used for expressing other powerful optimisations.

### **Block tiling**

Level-aware constructs can also be used for expressing other powerful optimisations.

Threads accessing same memory can cooperatively cache it in on-chip memory.

## Motivation for block tiling

map (
$$\x -> \text{redomap} (+) (\y -> y + x) 0 xs) xs$$

After flattening we get this inner-sequential version:

$$\textbf{segmap}_{thread} \ \langle \textbf{x} \in \textbf{xs} \rangle \ (\textbf{redomap} \ (+) \ (\lambda \textbf{y} \rightarrow \textbf{y} + \textbf{x}) \ \textbf{0} \ \textbf{xs})$$

Operation One thread for each element of xs, and each sequentially traverses xs.

Problem ?

## Motivation for block tiling

**map** (
$$\x -> \text{redomap} (+) (\y -> y + x) 0 xs) xs$$

After flattening we get this inner-sequential version:

$$\textbf{segmap}_{thread} \ \langle \textbf{x} \in \textbf{xs} \rangle \ (\textbf{redomap} \ (+) \ (\lambda \textbf{y} \rightarrow \textbf{y} + \textbf{x}) \ \textbf{0} \ \textbf{xs})$$

Operation One thread for each element of xs, and each sequentially traverses xs. Problem Poor utilisation of memory bus.

- Many threads simultaneously read same address, which is redundant.
- **Better:** *cooperatively* copy *block* into on-chip memory and iterate from there.

## Strip mining/chunking the outer segmap

$$\textbf{segmap}_{thread} \ \langle \textbf{x} \in \textbf{xs} \rangle \ (\textbf{redomap} \ (+) \ (\lambda \textbf{y} \rightarrow \textbf{y} + \textbf{x}) \ \textbf{0} \ \textbf{xs})$$

Assuming we can split xs into m equally sized *tiles* each of size t, giving xss: [m][t]f32, then we can rewrite to

$$\begin{split} \textbf{segmap}_{block} & \left< xs \text{'} \in xss \right> \\ \textbf{segmap}_{thread} & \left< x \in xs \text{'} \right> \\ \textbf{redomap} & \left( + \right) \left( \lambda y \rightarrow y + x \right) 0 \text{ } xs \end{split}$$

Question: does this compute the same value as the original?

## Strip mining/chunking the outer segmap

$$\textbf{segmap}_{thread} \ \langle \textbf{x} \in \textbf{xs} \rangle \ (\textbf{redomap} \ (+) \ (\lambda \textbf{y} \rightarrow \textbf{y} + \textbf{x}) \ \textbf{0} \ \textbf{xs})$$

Assuming we can split xs into m equally sized *tiles* each of size t, giving xss: [m][t]f32, then we can rewrite to

$$\begin{split} \textbf{segmap}_{block} & \left< xs \text{'} \in xss \right> \\ \textbf{segmap}_{thread} & \left< x \in xs \text{'} \right> \\ \textbf{redomap} & \left( + \right) \left( \lambda y \rightarrow y + x \right) 0 \text{ } xs \end{split}$$

#### Question: does this compute the same value as the original?

- No—the original expression had type [n]f32, while this has type [m][t]f32
- This can be flattened away.

```
\begin{array}{l} \textbf{segmap}_{block} \; \langle \textbf{xs'} \in \textbf{xss} \rangle \\ \textbf{segmap}_{thread} \; \langle \textbf{x} \in \textbf{xs'} \rangle \\ \textbf{redomap} \; (+) \; (\lambda \textbf{y} \rightarrow \textbf{y} + \textbf{x}) \; \textbf{0} \; \textbf{xs} \end{array}
```

Chunking/strip-mining the **redomap**, we get

```
\begin{array}{l} \textbf{segmap}_{block} \; \langle \textbf{xs'} \in \textbf{xss} \rangle \\ \textbf{segmap}_{thread} \; \langle \textbf{x} \in \textbf{xs'} \rangle \\ \textbf{loop} \; \textbf{acc} \; = \; 0 \; \textbf{for} \; \textbf{ys} \; \textbf{in} \; \textbf{xss} \; \textbf{do} \\ \textbf{redomap} \; (+) \; (\lambda \textbf{y} \rightarrow \textbf{y} + \textbf{x}) \; \textbf{acc} \; \textbf{ys} \end{array}
```

```
\begin{array}{c} \textbf{segmap}_{block} \; \langle \textbf{xs'} \in \textbf{xss} \rangle \\ \textbf{segmap}_{thread} \; \langle \textbf{x} \in \textbf{xs'} \rangle \\ \textbf{redomap} \; (+) \; (\lambda \textbf{y} \rightarrow \textbf{y} + \textbf{x}) \; \textbf{0} \; \textbf{xs} \end{array}
```

Chunking/strip-mining the **redomap**, we get

```
segmap_{block} \langle xs' \in xss \rangle
                           seqmap_{thread} \langle x \in xs' \rangle
                               loop acc = 0 for ys in xss do
                                  redomap (+) (\lambda v \rightarrow v + x) acc vs
Distributing and interchanging segmap<sub>thread</sub> gives
                        segmap_{block} \langle xs' \in xss \rangle
                            loop accs = replicate t 0
                            for vs in xss do
                              segmap_{thread} \langle x, acc \in xs', accs \rangle
                                 redomap (+) (\lambda v \rightarrow v + x) acc vs
```

```
\begin{array}{l} \textbf{segmap}_{block} \; \langle \texttt{xs'} \in \texttt{xss} \rangle \\ \textbf{loop} \; \texttt{accs} \; = \; \texttt{replicatet0} \\ \textbf{for} \; \texttt{ys} \; \textbf{in} \; \texttt{xss} \; \textbf{do} \\ \textbf{segmap}_{thread} \; \langle \texttt{x}, \texttt{acc} \in \texttt{xs'}, \texttt{accs} \rangle \\ \textbf{redomap} \; (+) \; (\lambda \texttt{y} \to \texttt{y} + \texttt{x}) \; \texttt{acc} \; \texttt{ys} \end{array}
```

Collectively copy ys to shared/local memory

```
\begin{array}{l} \textbf{segmap}_{block} \; \langle \textbf{xs'} \in \textbf{xss} \rangle \\ \textbf{loop} \; \textbf{accs} \; = \; \textbf{replicate} \; \textbf{t} \; \textbf{0} \\ \textbf{for} \; \textbf{ys} \; \textbf{in} \; \textbf{xss} \; \textbf{do} \\ \textbf{let} \; \textbf{ys'} \; = \; \textbf{copy} \; \textbf{ys} \; \textbf{in} \\ \textbf{segmap}_{thread} \; \langle \textbf{x}, \textbf{acc} \in \textbf{xs'}, \textbf{accs} \rangle \\ \textbf{redomap} \; (+) \; (\lambda \textbf{y} \rightarrow \textbf{y} + \textbf{x}) \; \textbf{acc} \; \textbf{ys'} \end{array}
```

- Now the many iterations of the **redomap** read from fast on-chip memory rather than slower global memory!
- copy done collectively by all threads in group

## The fine print

```
\begin{array}{l} \textbf{segmap}_{block} \; \langle x \textbf{s} \; ' \in x \textbf{ss} \rangle \\ \textbf{loop} \; \textbf{accs} \; = \; \textbf{replicate} \; \textbf{t} \; \textbf{0} \\ \textbf{for} \; \textbf{ys} \; \textbf{in} \; \textbf{xss} \; \textbf{do} \\ \textbf{let} \; \textbf{ys} \; ' = \; \textbf{copy} \; \textbf{ys} \; \textbf{in} \\ \textbf{segmap}_{thread} \; \langle x, \textbf{acc} \in x \textbf{s} \; ', \textbf{accs} \rangle \\ \textbf{redomap} \; (+) \; (\lambda \textbf{y} \rightarrow \textbf{y} + \textbf{x}) \; \textbf{acc} \; \textbf{ys} \; ' \end{array}
```

- Very simple case (e.g. xss traversed in both loops)
- 2D tiling much more complex
- The tile size t is a sensitive tuning parameter; in this case it should coincide with workgroup size
- Appreciate what a compiler can do for you

### **Summary**

- There is no one size fits all: for optimal performance, we need different amounts of parallelisation for different workloads.
- Incremental flattening generates a single program that for varying datasets exploits only as much parallelism as profitable.
- Autotuning for specific hardware and program is needed to select the optimal version at runtime.
- A good IR is as crucial to a compiler as a good language is to a human.
